1 Introduction

We are going to construct now a template or sample document which covers the main tools that one needs to produce a complex L^AT_EX document. Most of the things that you will ever need and many more are covered throughly in [2]. In the next lecture we are also going to cover some more advanced material to understand how the internals of L^AT_EX work. This is rarely used directly but it helps to understand why L^AT_EX does things the way it does and it saves time. All the details can be found in the book by the father of T_EX, D. Knuth [1].

2 The Preamble

The very first four lines of your document should be the following.

```
% !TEX encoding = UTF-8 Unicode
\documentclass...

\usepackage[utf8]{inputenc}
\usepackage[T1]{fontenc}
```

The first line, including the comment, must be line 1 in the source file. These three lines together make unicode encoding and fonts work natively in the document. This way you do not need to care about special characters like é í ã ó. They will work as expected.

The preamble is the place in the source file between these lines and the `\begin{document}` statement. All the packages to be used in a document should be called there. Check the preamble of this file to get an idea of its typical structure.

3 Title and other headings

The formatting of the title and other headings depends on the class, as many others. They can be modified by redefining the corresponding macros. Typically the style and macros used to define the headings of the document depend on the journal or editorial where you will publish the document. The article class (as well as book and report) include a simple way of producing this heading. There are some macros like `\author`, `\title`, `\date` which then are transformed using the `\maketitle` command. In the article class the `\maketitle` needs to be included after the `\begin{document}` statement. The rest of the macros will go typically in the preamble. Check how they are used in the source file.

4 Table of contents

5 Mathematics in a Document

5.1 The math modes and the text mode

Typesetting mathematics in a document was one of the reasons why \TeX and later \LaTeX was created. There are two types of math modes: inline mode and displayed mode. Inline mode is when an equation or mathematical expression is embedded in the text, $\sum_{j=1}^{n=10} x^j$, like this one. It is included in the source text with the symbol `$`. A single `$` starts the inline math mode and another `$` ends it. Another way of inserting math in the inline mode is surrounding it with the symbols `\(, \)`, like here $\lim_{x \rightarrow \infty} f(x) = 7$. The math mode and the text mode have many differences. For instantes, regular latin characters are displayed in italics and spaces are ignored *Thisismathmode*. Display mode can be called

using double dollar symbols $\$, \$$ or enclosing it with $\[, \]$ like here

$$\sum_{j=1}^{n=10} x^j$$

or

$$\lim_{x \rightarrow \infty} f(x) = 7.$$

As opposed to inline math mode, the displayed mode prints the mathematical expression in a separated line. Whether this equation is centered, right aligned or left aligned depends on the class and styling. Notice that there are differences in how the math is typeset in the two modes. The inline mode is more compact and sub and superscripts are placed at different positions.

5.2 Some environments useful for presenting equations

The equation environment.

It includes automatically a tag for the equation. Look at the number at the margin. The number can be associated to a label with the `\label` command.

$$\int_{-\infty}^{\infty} e^{-x^2} dx = \sqrt{\pi} \tag{1}$$

I can refer to point to the equation 1.

The align environment.

The following environments require the `amsmath` package. It is loaded in the preamble. The `align` environment is useful to typeset many equations together. Each equation gets its own tag. You can prevent an equation from getting a tag by using the `\notag` command.

$$(a + b)^2 = a^2 + 2ab + b^2 \tag{2}$$

$$\geq 0 \tag{3}$$

$$> -x^2 + 5$$

The starred version, `align*`, produces the same output but introduces no tags.

$$(a + b)^2 = a^2 + 2ab + b^2$$

$$\geq 0$$

$$> -x^2 + 5$$

5.3 Tabular math

Matrix-like environments use `\\` to separate rows and `&` to separate columns. Different brackets can be chosen:

$$A = \begin{bmatrix} a & b \\ c & d \end{bmatrix} \neq \begin{matrix} a & b \\ c & d \end{matrix} \neq \begin{pmatrix} a & b \\ c & d \end{pmatrix}$$

Another common matrix-like environment is the `cases` environment.

$$f(x) = \begin{cases} \exp\left(-\frac{1}{x}\right) & , \text{ if } x > 0 \\ 0 & , \text{ if } x \leq 0 \end{cases}$$

6 Tables in text mode. The tabular environment

One can produce tables in latex. We will speak about the basic functionality. The functionality can be extended by using packages that can be loaded in the preamble. There is a mandatory argument that specifies the alignment of each column. The pipe | in the argument determine wheter to split the adjacent columns by a vertical line.

Aligned left	An Oak	Aligned right	An Oak
\emptyset	Centered	\emptyset	Centered
\emptyset	\emptyset	\emptyset	\emptyset

7 List environments

- First element
 - Second element
1. First element
 2. Second element
1. First element
 - (a) element 1.1
 - i. element 1.1.1
 - ii. element 1.1.2
 - iii. element 1.1.3
 - (b) element 1.2
 2. Second element

The labels of the nested enumerate environment can be changed. This is done with the special commands `\labelenumi`, `\labelenumii`, `\labelenumiii`, `\labelenumiv`, `\theenumi`, `\theenumii` and so on. The i's determine the nesting level in roman numbers. Check the code to see how to change the labels.

- b
 - iii
 - II
1. First element
 - (I) element 1.1
 - i. element 1.1.1
 - ii. element 1.1.2
 - iii. element 1.1.3
 - (II) element 1.2
 2. Second element
 1. First element

- I]] -> element 1.1
 - i. element 1.1.1
 - ii. element 1.1.2
 - iii. element 1.1.3

II]] -> element 1.2

2. Second element

We will see more functionality of the command `\renewcommand`. This is very useful and a must-to-know for every \LaTeX user.

8 Changing Fonts in a \LaTeX Document

- Series
 - Bold; **I am Bold; I am bold**
 - Medium(default); I am normal; I am normal ; I am normal
This is bold this is not
- Family
 - Serif font (default); Here am I ; Here am I;
 - Sans Serif font; Here am I; Here am I
 - Typewriter font; `text`; Here am I
- Shape
 - upright (default); Normal; also normal
 - slanted/italics; *I am in italics*; *Also in italics*
 - small caps: I AM IN SMALL CAPS; I AM ALSO

You can mix the three properties, some particular combinations might not be available: Hello *Hello Hello* **Hello Hello** Hello

9 Defining macros

You can define your own macros. This is done with the following commands:

`\newcommand{\newcommandname}{code to be substituted when \newcommandname is written}`
`\renewcommanddots`

The difference between them is that they check if a given command is already defined. To override an already defined command you need to use `\renewcommand`.

I will define the following macro: `\newcommand\R{\mathbb{R}}`

The `mathbb` command requires the `amsfonts` package.

\mathbb{R}

Commands with arguments

The number of arguments is determined with square brackets. The arguments are called within the macro prepending a #. Check the code.

$\langle A \rangle$

$\frac{\text{Numerator}}{\text{Denominator}}$

10 Including Graphics

Figure 1: Some descriptive text

11 The Minipage environment

This environment allows you to define a box of text on which you can define width. The second paragraph below is within a *minipage* environment.

Let us see how long are the lines now. ewf wefe2f we wef weof wef we we ew wef wef w wef efwef wefjwnñklwef wje fwejfw lkejlweñkjef welñk lwej

lwek jelñwfj wlñke wel jwel jñlwej lñwejfl kenfwejfl lñwejflwekjf wefkljwe welkjf
wlkjfwlekej flwe lkwldflk weklf w

Let us see how long are the lines now.

wef w wef efwef wefjwnñklwef wje fwe-
jfw lkejlweñkjef welñk lwej lwek jelñwfj
wlñke wel jwel jñlwej lñwejfl kenfwejfl
lñwejflwekjf wefkljwe welkjf wlkjfwlekej
flwe lkwldflk weklf w

12 Defining a bibliography with ‘Bibtex’

We have referenced the bibliography previously, like here [3]. With \LaTeX one can use an automated tool to generate the bibliography, this is called ‘Bibtex’. For doing it one needs to include the two statements that can be found after this paragraph. The source document needs to be parsed several times to complete the process. This is so because first one needs to know which references in the ‘.bib’ file are cited in the document. Then a formatted bibliography file ‘.bbl’ is created. Then the bibliography file is read and included in the document. Finally you need to run latex again to get the references properly. In summary, whenever you add some `\cite` references to the document you need to compile with latex, then ‘Bibtex’ and then with \LaTeX two times again.
